Somatic variant calling studies often include many patients with dataset sizes varying widely between oncopanel, whole-exome, and whole-genome sequencing data. nf-core¹ provides reproducible, scalable, and portable open-source Nextflow²-based pipelines. nf-core/sarek³ is an established pipeline for exploring single-nucleotide variants, structural variation, microsatellite instability, and copy-number alterations of germline, tumor-only, and paired tumor-normal short-reads. Here, we show the latest updates to the pipeline including improvements to the data flow and tool selection reducing time and compute resources and, modularization improving maintainability.

PIPELINE OVERVIEW

OPTIMIZING DATA FLOW

- FASTQ or BAM inputs are split into files of equal size before alignment.
- Resulting BAM files are then merged and duplicate marked in one step before they are converted into CRAM format.
- Subsequent steps are run on multiple genomic regions in parallel. By default for WGS a interval file with used with chromosomes cut at their centromeres, for WES or panel data a user-supplied target bed file is used.
- For all data types, small regions are collected resulting in approximately equal sizes being processed together.

RESULTS

- Somatic variant calling on 41 tumor/normal pairs, panel data, 708 genes
- Adapters trimming (trimgalore vs fastp), bwa, duplicate marking, BQSR, Strelka, Manta, VEP, all available QC steps respectively
